Case for business analysts. Financial Shield.

1. The concept

Financial Shield is a feature that adapts to the user to provide effective, personal, unobtrusive financial protection.

2. How it works

When a user makes a large transaction (a transfer, investment trade, loan, etc.), the feature analyzes more than 30 parameters grouped into 5 categories and asks the user 2-3 of the most relevant questions. Depending on the calculated risk level, the following happens:

- **Low risk:** the transfer proceeds without intervention.
- **Medium risk:** a yellow warning indicator and a comment explaining the risk; a confirmation question ("Are you sure?").
- **High risk:** a red warning indicator and a comment explaining the high risk; 2-3 clarifying questions; a banner with information about similar fraud cases and a short delay; the option to cancel the transaction within 5-10 seconds immediately after confirmation.

This helps users avoid financial mistakes and distinguish deliberate transactions from impulsive and fraudulent ones. It also encourages users to consider whether the transaction is financially sound, without irritating them or restricting their freedom.

Important: a transfer or purchase is never blocked completely. The user can always select "Transfer anyway".

3 and 5. User scenarios

Oleg, 25, esports player (clickable)
Situation: Oleg finds an advertisement for a PlayStation 5 for RUB 20,000 - half the market price. The seller writes: "100% payment in advance, right now, or I will sell it to someone else."

Excited, Oleg wants to pay in advance. The recipient is new, and RUB 20,000 is higher than Oleg's usual transaction amount. The feature shows a red indicator and asks about the purchase: "Have you already received the goods or service?" - "No"; "Have you seen the seller in person or on video?" - "No"; "Are you being rushed?" - "Yes". The system warns of fraud and pauses the transfer for a while. Oleg reads about a situation exactly like his and realizes it is a scam.

Dima, 22, student
Situation: a stock has risen by 35% in one day. Dima wants to spend his remaining RUB 30,000 on it because he is afraid of missing out. His rent is due tomorrow.

He opens his account and is ready to invest all his savings. The system asks: "Are you buying because of the sharp price rise?" - "Yes"; "Will you need this money in the next few days?" - "Yes". It displays: "It is better to invest only spare money that you can afford to lose. FOMO often leads to poorly considered decisions," and introduces a delay. Dima postpones the purchase; two days later, the stock falls by 20%.

Anna, 23, traveler
Situation: during an overnight layover at an airport, Anna decides to buy her mother a birthday gift. The feature displays a warning. Anna proceeds with the transfer and walks away with the gift five seconds later. Financial Shield does not get in the way even in cases like this.

4. Parameters and data analyzed by the feature

- **Transaction parameters:** transaction amount, recipient analysis, transfer purpose, transfer currency, and transaction type.
- **Behavioral parameters:** transaction date and time, input characteristics, device, and location.
- **Investment parameters:** purchase size, stock price movements, signs of FOMO, use of money needed for other purposes, and investment horizon.
- **Profile parameters:** user age, experience using the app, and history of mistakes.
- **Psychological parameters:** emotional state, awareness of transaction safety, financial literacy, and awareness of one's actions.

6. Impact, success metrics, and value

How does the proposed feature affect the rest of the product?

- **Onboarding:** a new user sees a demonstration of how the protection works.
- **Settings:** the level of intervention can be configured (disable questions or change the timer).
- **Support:** fewer inquiries about disputed transactions.
- **Analytics:** new metrics become available.

How will you measure success after implementing the new feature?

Using the following metrics: the number of fraudulent transactions, the share of cancellations after a warning, the number of false positives, and the number of users who disable the feature.

If another team says its feature is better and yours is unnecessary, how will you demonstrate otherwise?

- **Greater trust:** users lose money less often and recommend the app to friends more often.
- **Reduced support workload:** fewer inquiries about disputed transactions.
- The feature becomes part of the brand: "a smart and safe service".
- **Adaptability:** it does not irritate experienced users and protects beginners.
- Tracking false positives makes it possible to improve the model and protection over time.
- I will show specific cases where users avoided harm: stories of users who canceled a transfer after a warning.
- The feature reduces the risk of complaints and reputational damage.
